1. Introduction

1.1. Purpose of this document

This document is an Annex to the Application for Full Approval and details the economic appraisal of the A6 to Manchester Airport Relief Road (A6MARR) scheme.

1.2. Overview

The A6 to Manchester Airport (A6MARR) scheme has been identified by Central Government as one of a number of nationally important infrastructure projects, which are required to revitalise the economy and provide congestion relief to local communities.

The A6MARR scheme will improve surface access to Manchester Airport and provide better connectivity along the south Manchester corridor, to assist Greater Manchester and Cheshire East in meeting their aspirations for economic growth. It directly supports the Government's objective to provide major transport infrastructure that will deliver economic growth, a fact acknowledged by the announcement on prioritisation for funding in the Chancellor's Autumn Statement in November 2011. The scheme will provide congestion relief to local communities and generate wider benefits to business through improved journey time reliability on the local and strategic highway network.

The A6MARR scheme is an integral component of the wider South East Manchester Multi-Modal Strategy (SEMMMS), which has delivered benefits to local communities across south-east Manchester through a range of public transport and sustainable transport measures over the past ten years. It is widely recognised that the A6MARR scheme is critical to delivering the long-term objectives of the SEMMMS strategy, and to meet national objectives for growth, employment and connectivity.

1.3. About the Scheme

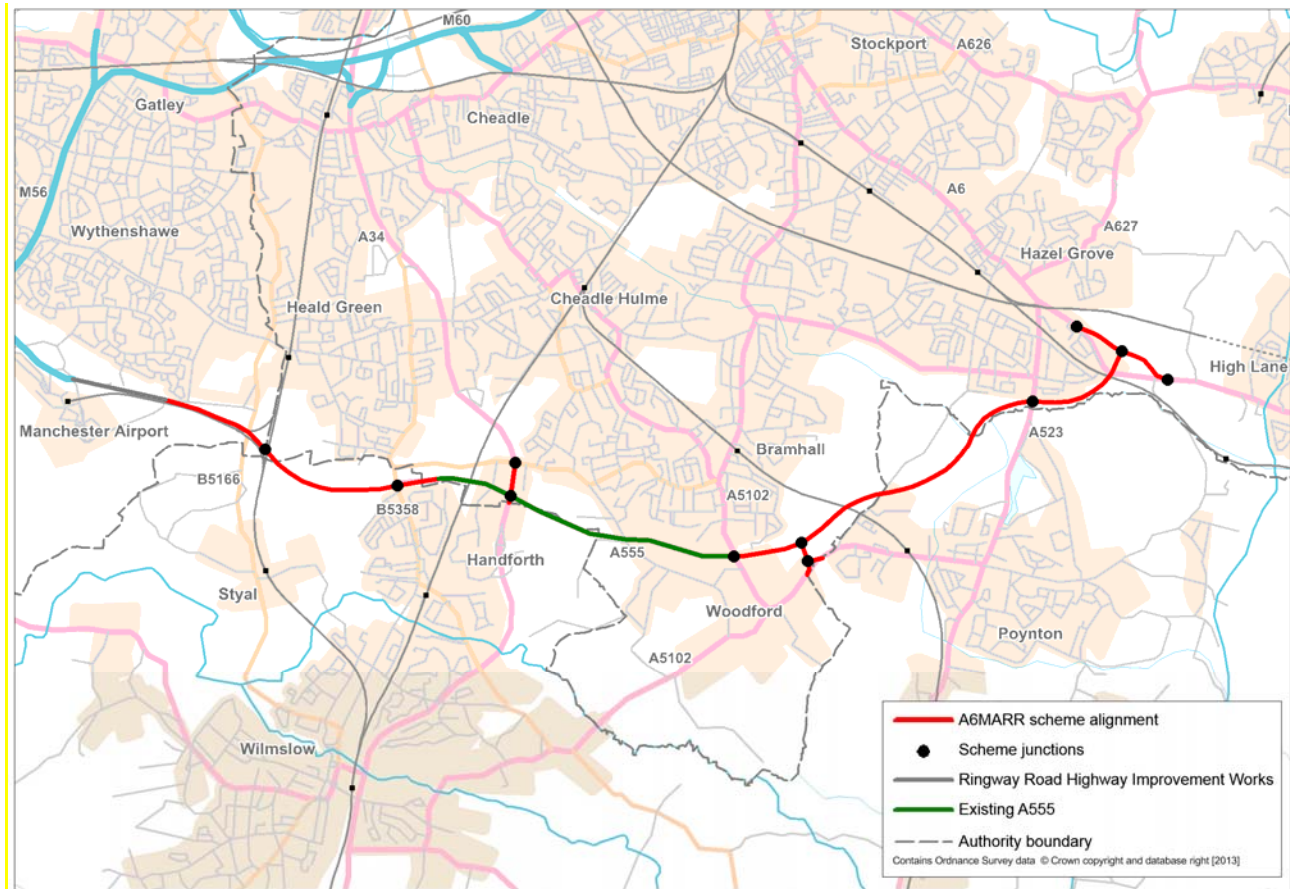

The A6MARR scheme will provide 10 kilometres of predominantly new 2-lane dual carriageway running east-to-west from the A6 near Hazel Grove (south-east Stockport), via the 4 kilometres of existing A555 to Manchester Airport and the link road to the M56 spur.

The A6MARR scheme bypasses heavily-congested district and local centres, including; Bramhall, Cheadle Hulme, Hazel Grove, Handforth, Poynton, Wythenshawe, Gatley and Heald Green. It will provide much-needed connectivity for key strategic routes into the North West and to Manchester Airport, including traffic from the A6, A523 and A34 – all of which are key routes for business, leisure travel and freight from Cheshire, Derbyshire, Staffordshire, Yorkshire and beyond. The A6MARR scheme incorporates seven new and four improved junctions, four railway crossings and a parallel shared cycle/ pedestrian path.

1.4. Scheme Location

Figure 1.1 shows the location of the proposed scheme. The specific components of the scheme are presented in more detail below.

Figure 1-1 Location of the SEMMMS A6 to Manchester Airport Relief Road Scheme

1.5. Scheme Description

The scheme is a new 2-lane dual carriageway with a shared use cycle/ footway constructed to urban standards, orientated on an east-west route from the A6 near Hazel Grove (south east Stockport), via the 4 kilometres of existing A555 to Manchester Airport. It passes through three local authority areas Cheshire East, Stockport and Manchester City Councils.

The proposed development comprises three sections. The first section is approximately 5.1km in length, starting from a new realigned section (approximately 1km long) of the A6 at Hazel Grove, and extending west to the existing A555 at Woodford Road, Bramhall. The second section is the new shared use cycle and footpath/ bridleway adjacent to the existing A555. The third new section is approximately 3.2 km in length and is an extension of the existing A555 that currently terminates at Wilmslow Road. The route continues in a westerly direction crossing Styal Road and heading towards Manchester Airport to the junction at Ringway Road and Ringway Road West. The proposed development also incorporates remodelling works at Stanley Green roundabout and highway improvements on the A34 from Stanley Green roundabout to the A34/ A555 junction. The route utilises the existing A555 which is approximately 4.0km in length.

The proposed development incorporates seven new and four improved highway junctions, including at-grade, grade separated, signalised controlled and priority junctions, roundabout, T-Junction and cross road arrangements. The route of the proposed road crosses four railway lines, one of which is the West Coast Mainline (WCML). Provision for pedestrians and cyclists has been included along the entire length of the proposed development through a segregated multi-user cycle/pedestrian route adjacent to the new road and existing length of the A555 and within the design of every junction.

The development will also be accompanied by a package of complementary and mitigation measures which are closely associated with the successful scheme delivery and which have been identified to improve the local road network and off-set the potential localised traffic impact of the new road. These measures have

been proposed to address the predicted change in traffic flow on the local highway network following completion and opening of the A6MARR scheme. The measures aim to ameliorate the scheme's impact on local communities where there are predicted to be traffic increases, and seek opportunities to encourage walking, cycling and support to local centres where there are predicted to be reductions in traffic flow.

Cheshire East Council, Derbyshire County Council, Manchester City Council and Stockport Council being mindful to ensure that the programme for commencement of the Relief Road is achieved at the earliest opportunity and completed by Summer 2017 have in their separate capacities as local highway authorities agreed to enter into a Delivery Agreement to try to ensure that there are no planning obstacles that might otherwise fetter or frustrate completion of the A6MARR.

1.6. Structure of the Report

The development of the base and forecast year traffic models on which this economic assessment is based are discussed in the Model Development Report and the Model Forecasting Report. This Economic Assessment Report presents the methodology and assumptions adopted for the economic assessment, and the results provided thereof. Following this introduction, the remainder of the report is structured as follows:

- Chapter 2 describes the Methodology & Assumptions underpinning the economic assessment;
- Chapter 3 presents the Economic Assessment Results for the proposed A6MARR scheme.
- Appendix A contains the Transport Economic Efficiency (TEE) Tables;
- Appendix B provides details of the Derivation of Annualisation Factors, which are used to extrapolate modelled economic benefits across the year;
- Appendix C contains Figures and Matrices of Sectorised Benefits, which provides a detailed breakdown of the time savings, vehicle operating cost savings and total present value of benefits generated between different sectors of the traffic model, for all modelled time periods and years.

2. Assessment Methodology & Assumptions

2.1. Overview

The economic assessment has primarily been conducted using the Department for Transport's (DfT) TUBA¹ software, which calculates monetised benefits and costs relating to travel time, vehicle operating costs, indirect tax revenue and user charges. TUBA produces a summary of these results in the form of a Transport Economic Efficiency (TEE) Table, copies of which are presented for each scenario in Appendix A of this report. The current version of TUBA is 1.9.4, which has been used for this assessment.

Cost savings resulting from reduced accident levels following the implementation of the scheme, have been assessed using principles derived from the DfT's COBA² software. Accident rates are attributed to different link types and the forecast changes in traffic flows are used to estimate the changes in accident numbers and the severity of the accidents.

2.2. Methodology

2.2.1. Traffic modelling

A robust approach to scheme assessment has been undertaken, using a variable demand modelling framework originally developed for the Greater Manchester Transport Innovation Fund (TIF) work, but updated specifically for the SEMMMS A6 to Manchester Airport Relief Road scheme. The modelling suite was developed jointly by Transport for Greater Manchester (TfGM formerly the Greater Manchester Transportation Unit – GMTU) and the SYSTRA Consultancy (formerly MVA Consultancy). Additional modelling input and a formal reviewing role was provided by Atkins.

The model captures origin-destination trip and cost data across the extent of the UK, with detailed simulation modelling across Greater Manchester, Cheshire and the surrounding environs.

Models were created to represent three time periods:

- Morning peak (0700-1000);
- Inter-peak average hour (1000-1600); and
- Evening peak hour (1600-1900).

The model developed for GMTIF work had a base year of 2007. The A6 to Manchester Airport Relief Road model has been updated with a base year of 2009. The model was calibrated and validated in accordance with DfT criteria using observed traffic count and journey time data collected in neutral months throughout 2009. Full details of the data used to develop, calibrate and validate the base year transport model are presented in the **A6MARR Data Collection and Traffic Surveys Report**.

All modelled time periods pass the calibration and validation criteria and are deemed to provide a good representation of observed traffic conditions across the study area. Full details of the calibration and validation methodology and outputs are provided in the **A6MARR Local Model Validation Report**. Full details of the demand model are provided in the **A6MARR Model Development Report**.

Model forecasts were prepared for two future years: 2017 and 2032. The transport network and public transport services have been updated to reflect schemes under construction and committed transport options anticipated to be in place by 2017 and 2032 respectively.

Future year forecast models were produced for the following scenarios:

¹ TUBA - Transport User Benefit Appraisal (Economic Appraisal Software developed by Mott MacDonald on behalf of the Department for Transport)
² COBA - Cost Benefit Analysis (Department for Transport sponsored program maintained and distributed by TRL)

- A Do-Minimum (DM), which contains all committed developments and committed transport schemes (highway and public transport) across the study area to 2032; and
- A Do-Something Preferred Option (PO), which includes all developments and schemes from the DM, plus the A6MARR scheme.

Assumptions on population and employment growth used to derive the Core forecasts are based on a variety of sources, namely:

- Relevant planning departments in High Peak, Cheshire East, Manchester, Stockport, Trafford for specific developments included in their Local Development Frameworks;
- Manchester Airport Group (MAG) for passenger and employee growth and development at and around Manchester Airport;
- Local Development Framework datasets for developments elsewhere in Greater Manchester;
- National Trip End Model (NTEM) dataset 6.2 forecasts; and
- National Transport Model forecasts (for freight traffic).

The methodology used to derive the Core forecasts involves:

- Extracting population and employment forecasts from the work undertaken to assess the transport impacts of the Greater Manchester Local Development Frameworks;
- Replacing the GM LDF forecasts for Manchester, Stockport and Trafford with revised forecasts based on the District planning data;
- Overwriting NTEM forecasts for High Peak and Cheshire East with revised forecasts based on local planning data;
- Constraining the population and employment growth forecasts to the overall growth level implied by NTEM 6.2 at the district level within Greater Manchester the pre-2009 district level for Cheshire East and at the county level elsewhere; and
- Applying the External Forecasting Model to produce forecasts of the future year travel demand for input to SEMMMS VDM from the population and employment forecasts.

The demand model was run for the DM and PO scenarios, to enable any variation in traffic due to the scheme (induced traffic) to be reflected in the appraisal.

Whilst the core scenario represents the most unbiased and realistic set of assumptions that form the central case, sensitivity tests have been undertaken to confirm the robustness of the business case and reflect potential risks around benefits.

High and low growth alternative scenarios have been undertaken to test the impact of the scheme to high and low background traffic growth, based on national WebTAG guidance. Additionally these include local assumptions about demand where:

- The high growth scenario includes some of the most likely sources of growth (development that is considered to be reasonably foreseeable) and which have not been included in the core scenario (i.e. development that is considered to be either near certain or more than likely); and
- The low growth scenario excludes some of the less likely sources of growth (development that is considered to be more than likely) and which were included in the core scenario.

Further details of the development of the future year forecast models, and the impact of the PO relative to the DM, are presented in the **A6MARR Model Forecasting Report**.

2.2.2. Appraisal Periods

Economic benefits of the scheme have been quantified using the DfT's Transport User Benefit Appraisal (TUBA v1.9.4) software.

Outputs from the SATURN³ traffic models were provided, giving details of demand, journey times, trip distances and charges or fares applicable to those trips. These were generated as matrices with average figures for each origin-destination pair and were provided for both modelled years, 2017 and 2032, and for three time periods, AM, inter-peak and PM in each year.

Economic benefits are calculated for five modelled time periods. In order to establish the 'true' impact of the proposed scheme, it is necessary to extrapolate these benefits across a whole year, using appropriate annualisation factors. This follows the standard assumption that the travel patterns and scheme benefits observed in a modelled hour are an accurate representation of similar time periods on different days throughout the year. That is, the traffic model does not represent any one specific day in the year, but can be taken as representative of any day throughout the year.

Annualisation factors for expanding modelled benefits across the year can be based on default values as recommended in the TUBA guidance, or on locally-observed traffic data. In cases where AM, inter-peak and PM peak models represent an average hour during each time period, default factors are easy to justify. The AM and PM peak periods are assumed to represent the periods 0700-1000 and 1600-1900 respectively, that is, three hours in each peak period. A factor of three would be applied to an AM/PM average hour model, to reflect the fact that average conditions occur on three hours of the day. Assuming 253 working days across the year (365 days less 104 weekend days and 8 Bank Holidays), an annualisation factor of 759 would be adopted for the AM and PM models (253 days x 3 peak hours).

The inter-peak is represented by the period 1000-1600, that is, a six-hour period, so total daily inter-peak benefits would be derived by applying a factor of 6 to the inter-peak modelled hour benefits. Assuming the same 253 working days across the year, a factor of 1518 would be adopted for the inter-peak (253 x 6 inter-peak hours).

For the A6 to Manchester Airport Relief Road Scheme, default values would be potentially misleading for the AM peak traffic model, as they represent the single peak hour, rather than average morning peak traffic conditions. In such instances, the benefits generated by the scheme proposals are likely to be overestimated, as peak hour conditions are unlikely to be replicated for all three hours of the AM peak period. The factor used to annualise peak hour modelled benefits, therefore, is lower than the default factors one would apply to 'average hour' models, as it takes into account the higher than average proportion of traffic in the peak hour relative to the respective three-hour peak periods.

For the inter-peak and PM Peak average hour models, however, the default factor of 1518 and 759 respectively are valid as they are based on an average of inter-peak and PM peak hours and have therefore been adopted for this assessment.

Annualisation factors for a Saturday and an off peak week day period of 19:00 – 07:00 have also been calculated and used as part of the TUBA assessment.

The annualisation factors used for each time period are as follows:

- Weekday AM Peak: 672;
- Weekday PM Peak: 759;
- Weekday Inter-Peak: 1518;
- Off Peak: 633; and
- Weekend: 520.

A description into the calculation of the annualisation factors used in this assessment is provided in Appendix B of this report. A detailed examination of the observed traffic flow profiles at various locations throughout the A6 to Manchester Airport Relief Route study area has been undertaken by Transport for Greater

3. Simulation and Assignment of Traffic in Urban Road Networks (Institute for Transport Studies, The University of Leeds)

Manchester and the conclusion is that the annualisation factors used for this Economic Assessment are valid.

Using the above methodology, benefits were calculated to show time benefits for highway and public transport users. Benefits were disaggregated by user type, with separate figures for business and non-business users.

Benefits reported included time savings, reductions in vehicle operating costs, savings in charges, such as public transport fares, changes in revenue to private operators and local government and reductions in carbon emissions.

These benefits were all monetised so that, based on values of time, the benefits of time savings could be added to the already monetised benefits of reduced operating costs and savings on fares.

TUBA calculates benefits over a 60-year period, discounted to a particular base year of prices. The current base as defined in the DfT's WebTAG guidance is 2010.

Similarly, both the accident analysis calculates costs and benefits over a 60 year assessment period, discounted to a price base year of 2010.

2.2.3. Terminology

The sum total of the aforementioned benefits is represented by the Present Value of **Benefits (PVB)**.

Scheme costs have been calculated for each 'Do Something' option, based on capital costs and the impact of the scheme on indirect tax revenues recouped by the government. The sum total of these scheme costs, over and above the corresponding 'Do Minimum' costs, is represented by the **Present Value of Costs (PVC)**.

The difference between the PVB and the PVC represents the **Net Present Value (NPV)** of the scheme.

The ratio of PVB to PVC produces the **Benefit-Cost Ratio (BCR)**. The BCR provides an indication of the value for money of a particular scheme. The DfT 'Guidance on Value for Money' states that a project will generally be:

- Poor value for money if the BCR is below 1.0;
- Low value for money if it has a BCR of between 1.0 and 1.5;
- Medium value for money if it has a BCR of between 1.5 and 2.0;
- High value for money if it has a BCR of between 2.0 and 4.0; and,
- Very High value for money if the BCR is greater than 4.0

2.3. Underlying Assumptions

2.3.1. Economic Parameters

The default economic parameters contained in the TUBA software have been used as the basis for the assessment. These parameters are based on DfT guidance as set out in TAG Unit A1.1 of WebTAG, and include data on the following:

- Values of time and value of time growth;
- Fuel costs, rates of fuel consumption and changes in vehicle efficiency over time;
- Vehicle occupancies;
- Journey purpose splits;
- Rates of taxation; and
- Carbon values for assessing the impact of the scheme on CO2 emissions.

2.3.2. Discount Rate

Discounting is the technique of comparing costs and benefits that occur in different years and involves the conversion to present values, so that they can be compared. It is based on the principle that, generally, society prefers to receive goods and services now, rather than later, and to defer costs to future generations - this is known as 'social time reference'.

The DfT's current standard rate of discount has been applied to scheme costs and benefits for this appraisal. The current guidance suggests the following rates of discount:

- 3.5% for the first 30 years of the appraisal period;
- 3% for years 31-75 of the appraisal period; and
- 2.5% beyond year 75.

The standard appraisal period for a scheme of this nature is 60 years, so only the first two discount rates apply in this instance.

3. Economic Assessment Results

3.1. Overview

This chapter presents the results of the economic assessment for the proposed A6MARR scheme for all scenarios.

A summary of the economic statistics for each forecast scenario is provided in Table 3.1, with full details provided in the TEE Tables in **Appendix A**. The summary statistics are consistent with the TEE Tables and therefore include accident benefits calculated outside of TUBA.

Table 3-1 Economic Summary Statistics for the Proposed Scheme

Economic Benefits & Costs by Forecast Scenario			
Economic Summary Statistic	Preferred Option	Low Growth Scenario	High Growth Scenario
PVB	£943.5m	£852.4m	£2,020.2m
PVC	£207.1m	£207.1m	£207.1m
NPV	£736.3m	£645.2m	£1,813.1m
BCR	4.55	4.12	9.75

From the summary statistics above it is clear that the Preferred Option, as well as the Low and High Growth scenarios would all bring substantial benefits and value for money. The value is reflected most clearly by the BCRs, with the preferred option exceeding a BCR of 4.0, offering 'very high' value for money, the Low Growth scenario achieves a BCR slightly exceeding 4.0, whilst the High Growth scenario substantially exceeds a BCR of 4.00, both sensitivity test scenarios achieve BCR's which represent 'very high' value for money against DfT guidelines.

Detailed discussion of the scheme costs and benefits is provided in this chapter. The scheme costs included in the assessment are set out in the following section, including an explanation of how the nominal scheme investment costs are adjusted to allow for future inflation, risk and optimism bias. Also included in the discussion on scheme costs are the potential indirect tax revenue (dis) benefits arising from the scheme, which contribute to the overall Present Value of Costs (PVC), reported in Table 3.1 and in the TEE Tables in **Appendix A**.

Following the discussion on scheme costs, the scheme benefits are presented for each forecast scenario. This includes discussion on the relative contribution of benefits relating to travel time and vehicle operating costs, as well as any reduction in accidents that may arise as a result of the scheme, which contribute towards the overall Present Value of Benefits (PVB) reported above.

3.2. Scheme Costs

3.2.1. Overview

For the purposes of economic appraisal, total scheme costs include the discounted cost of investment (and operating/maintenance costs, if applicable) and the impact of the scheme on indirect tax revenues. These elements are discussed in more detail below, with specific reference to derivation of scheme PVC for each of the proposed schemes.

There are three main elements of a scheme cost estimate:

- **Base costs**, which are the basic costs of the scheme before allowing for risks, but allowing for realistic assumptions of changes in real costs over time, such as cost increases above growth in the retail price index (RPI);

- **Adjustment for risk**, which should cover all the risks that can be identified, the majority of which then need to be assessed and quantified through a Quantified Risk Assessment (QRA). This results in the risk-adjusted cost estimate; and
- **Adjustment for optimism bias** to reflect the well-established and continuing systematic bias for estimated scheme costs and delivery times to be too low and too short respectively. This results in the risk and optimism bias-adjusted cost estimate.

3.2.2. Investment Costs

The base cost represents the basic costs of the scheme for a given price base, made up of base investment (or capital cost) and base operating costs (including all maintenance costs). It is a detailed estimate of the cost of the project, taking into account the amount by which any of the elements of the scheme's cost are expected to increase at a different rate to the general level of inflation across the economy. That is, the base cost represents scheme capital and operating costs expressed in real prices.

The inflation rates relevant to the delivery of transport schemes are currently higher than general inflation rates across the economy. This has a knock-on effect on the overall scheme cost and ultimately the value for money of the scheme.

3.2.3. Estimation of Scheme Costs

The Final Target Cost for the main Key Stage 6 contract is £92,475,083 and is based on a commencement date of 25 March 2015. The detailed cost estimate and QRA are attached as **Annex 3** and **Annex 4** to the Application for Full Approval respectively.

The following paragraphs give the details of how the scheme costs used in the economic analysis have been applied in TUBA.

Tag Unit A1.2 states: Only the costs which will be incurred subsequent to the economic appraisal and the decision to go ahead should be considered. 'Sunk' costs, which represent expenditure incurred prior to the scheme appraisal and which cannot be retrieved, should not be included. The costs of land or property purchased prior to an appraisal should be treated as sunk costs, unless the purchase costs could be recovered by the re-sale of the land or property if the scheme were not to go ahead. These should be based on current market values and not those incurred at the time of their acquisition, the value of expenditure prior to scheme appraisal classed as 'sunk' costs is £13.1 million.

The total capital cost of the scheme, including all land, preparation, maintenance, and supervision costs but excluding any future inflation, is £211.0 million at Q2 2014 prices.

Inflation has been applied to capital costs at 5.2% per annum, based upon long run RPI assumptions in government tender documentation of 2.5%, plus a 2.7% premium, based upon the Royal Institute of Chartered Surveyors (RICS) Building Cost Information Services (BCIS) Civil Engineering Index. These assumptions are in line with the assumptions used within the Greater Manchester Transport Fund (GMTF) financial strategy. The difference between land / construction sector inflation and economy-wide inflation has been applied to scheme costs for the purposes of economic appraisal.

Accordingly an allowance of £4.4 million for future inflation on construction and land prices has been made⁴, which produces a base cost valued at £215.3 million. In addition, we have included an allowance of £16.2 million for an increase in future maintenance costs associated with the new road as well as a cost profile for Street Lighting costs and renewals over the scheme assessment period.

Optimism bias has been applied to the preparation, supervision, construction and land costs. Based on the advanced stage of project development & design it is considered that the appropriate level of optimism bias is 3%, representing the upper bound limit for full approval. The total adjustment for optimism bias applied in the appraisal is £6.4 million.

The total cost used in the economic appraisal amounts to £221.8 million. This value has been input to TUBA to reflect the allocation of expenditure between Local and Central Government. The Local and Central

4. The difference between land / construction sector inflation and economy-wide inflation has been applied to scheme costs for the purposes of economic appraisal. This is different to the inflation that is applied for the calculation of scheme capital costs as part of The Financial Case, which include absolute inflation (i.e. including RPI).

Government costs, once converted to 2010 prices and values using the default rates included in TUBA, produce a PVC of investment of £207.1 million.

A breakdown of the Preferred Option scheme costs is given in Table 3.2 below. This provides detailed information on the final capital cost element of the scheme (Construction, Land Costs, Preparation, Maintenance and Supervision) and estimated scheme cost spend profile (from 2010 to 2076).

Table 3-2 Preferred Option Scheme: Components of Investment Cost (Q2 2014 Prices)

Year	Capital Costs (£m)					
	Construction	Land	Preparation	Maintenance	Supervision	Total
2010	-	-	-	-	-	0
2011	-	-	-	-	-	0
2012	-	0.04	-	-	-	0.04
2013	-	0.2	-	-	-	0.2
2014	48.5	9.8	0.3	-	0.1	58.7
2015	43.5	5.2	0.3	-	1.2	50.2
2016	62.7	2.2	0.2	-	1.2	66.3
2017	19.4	1.7	0.1	-	0.3	21.5
2018	1.6	22.4	0.6	-	-	24.6
2019 to 2076	-	-	-	14.2	-	14.2
Total	175.7	41.5	1.5	14.2	2.8	235.7

3.2.4. Present Value of Costs (PVC)

The individual components of the Present Value of Costs for the preferred option is shown in Table 3.3.

Table 3-3 Present Value of Costs (£000s)

Cost Type	Core
Operating Costs	1,277
Investment Costs	205,861
Total PVC	207,138

3.3. Scheme Benefits

3.3.1. Accident Benefits

The results of the accident analysis for the core scheme are presented in Table 3.4. For comparison, the number of accidents and casualties and the overall accident cost is summarised for the two model years and the for the whole 60-year appraisal period.

The A6MARR scheme (preferred option) will see a decrease of 556 accidents across the 60-year appraisal period, resulting in the following:

- 3 additional fatalities;
- A reduction of 17 serious casualties; and
- A reduction of 728 slight casualties.

In monetised terms, this produces a benefit of £23 million over the 60-year appraisal period.

Table 3-4 Accident Costs and Benefits for A6MARR Scheme Table

Do – Minimum			
	2017	2032	Total 60 year Appraisal Period
Number of Personal Injury Accidents	1,736	1,445	89,043
Casualties Fatal	19	15	918
Serious	243	197	12,180
Slight	2,055	1,714	105,557
Total Costs (£ms discounted to 2010 prices)	142	92	5,120
Do–Something			
	2017	2032	Total 60 year Appraisal Period
Number of Personal Injury Accidents	1,718	1,437	88,487
Casualties Fatal	19	15	921
Serious	241	197	12,163
Slight	2,032	1,703	104,829
Total Costs (£ms discounted to 2010 prices)	140	92	5,097
Benefits (Do–Something – Do–Minimum)

3.4. Scheme User Benefits

The following section details the economic benefits arising from the introduction of the Preferred Option, Low Growth and High Growth Scenarios of the A6MARR scheme.

3.4.1. Overview

A breakdown of the benefits generated by the proposed scheme is summarised in Table 3.5 below. As expected for a scheme of this nature, the majority of scheme benefits are generated in the form of time savings to highway users, accounting for up to 99% of total PVB.

Table 3-5 Proposed Scheme Total Economic Benefits by Forecast Scenario

Benefit	Economic Benefits by Forecast Scenario (£m)		
	Preferred Option	Low Growth	High Growth
Travel Time Savings	895.1	809.4	1,901.4
'VOC' Savings	7.2	11.9	88.0
Carbon Emission Savings	-10.7	-4.3	-2.7
Accident Savings	23	23	23
Indirect Tax	28.8	12.5	10.6
Net Present Value of Benefits (PVB)	943.3	852.5	2,020.3

It should be noted that the benefits presented in Table 3.1 relate to 'transport economic efficiency' TUBA based benefits alone (i.e. time savings and vehicle operating cost savings), so the total PVB figures are lower than those presented in the Table 3.5 above, as the latter include benefits relating to reductions in accidents and carbon emissions.

Table 3.6 gives the breakdown of benefits by journey purpose, the majority of benefits are accrued by 'business' travellers and 'other' users

Table 3-6 Distribution of TUBA Based Benefits Across User Types (£m)

Journey Purpose	PVB (£m)		
	Preferred Option	Low Growth	High Growth
Time Savings			
<i>Business</i>	317.1	302.3	686.1
<i>Commuting</i>	218.1	177.0	427.9
<i>Other</i>	359.9	330.1	787.3
Total	895.1	809.4	1,901.3
VOC Savings			
<i>Business</i>	37.9	31.2	90.3
<i>Commuting</i>	-2.1	-2.4	10.7
<i>Other</i>	-28.6	-16.9	-13.1
Total	7.2	11.9	88.0
Total PVB			
<i>Business</i>	354.9	333.5	776.5
<i>Commuting</i>	216.0	174.6	438.6
<i>Other</i>	331.3	313.2	774.2
Total	902.3	821.3	1,989.4

3.4.2. Temporal Distribution of Benefits

Table 3.7 provides a summary of the TUBA based PVB (excluding accidents and carbon emissions benefits) by time period, and the relative contribution of benefits from each time period to the total scheme benefits, over the 60-year appraisal period.

Table 3-7 Proposed Scheme TUBA Based PVB by Time Period

Time Period	Core Scheme		Low Growth Scenario		High Growth Scenario	
	£m	% of Total	£m	% of Total	£m	% of Total
AM Peak	312.0	35%	262.9	32%	585.9	31%
PM Peak	351.1	39%	285.3	35%	718.0	38%
Inter Peak	130.0	15%	146.3	18%	334.4	18%
Off Peak	54.4	6%	61.3	8%	140.2	7%
Weekend	47.6	5%	53.6	7%	122.8	6%
Total PVB	895.1	100%	809.4	100%	1,901.3	100%

Considering the 'preferred option' analysis then the PM peak period provides the largest element of benefit generated with 39%. The AM peak follows closely behind as the next largest contributor; accounting for 35% of total PVB and the inter peak generating 15%.

This temporal pattern of benefits is broadly followed by the A6MARR Low and High Growth scenarios, with the PM Peak period generating the largest element of scheme benefit varying from 35% for the Low Growth scenario and 38% for the High Growth scenario.

3.4.3. Public Transport Benefits

Based on a proportionate approach to scheme appraisal, benefits in terms of public transport user travel time savings have not been monetised as these are considered to represent a relatively small percentage of the overall benefits of the A6MARR scheme.

It is anticipated however that the new road will provide an opportunity for new bus routes to be considered to complement those that currently operate in the corridor.

As an example of benefits to bus users, the current bus services X69 and 369 have been analysed. Both these services run between Stockport town centre and Manchester Airport and would directly benefit from construction of the Relief Road. The two diagrams below show the current bus route for these services along with a proposed route following the opening of the Relief Road. Because of the changed local road configuration with the scheme, the proposed bus route is approximately 230m longer than the current route.

The DM and DS journey times have been extracted from the traffic models and are shown below in Table 3.8. The data shows that the journey time saving for this bus route is between 6% and 23% with the new Relief Road in place, representing a reduction in journey time of between one minute in the inter-peak period and up to seven minutes in the AM peak period. This analysis demonstrates that the Relief Road will, in reality, deliver significant benefits to public transport users in the scheme corridor.

Table 3-8 Bus Journey Time Savings

	AM				IP				PM			
	2017		2032		2017		2032		2017		2032	
	DM	DS	DM	DS	DM	DS	DM	DS	DM	DS	DM	DS
Westbound												
Time (secs)	1808	1488	1975	1641	1398	1253	1492	1326	1735	1492	1825	1527
Time (mins)	30.1	25.2	33.3	27.3	23.3	21.2	24.8	22.1	28.9	24.9	30.4	25.4
Time Saving		17.7%		16.9%		10.4%		11.1%		14.0%		16.3%
Eastbound												
Time (secs)	1605	1487	1812	1608	1267	1211	1341	1258	1626	1405	1936	1513
Time (mins)	27.1	25.2	30.2	27.2	21.1	20.1	22.3	20.9	27.1	23.4	32.2	25.2
Time Saving		7.4%		11.3%		4.4%		6.2%		13.6%		21.8%

As mentioned above, the relief road will open up the prospect of new bus services along the corridor utilising the new road. As no specific services are planned, no account has been taken of these potential services within the transport models or in scheme appraisal. There is however a real possibility that bus operators would seek to capitalise upon this new route corridor and operate commercial services between the town centres and the Airport. Typical bus services could include the following:

- Stockport town centre to Manchester Airport (via Hazel Grove and Bramhall). Currently a park and ride site at Hazel Grove is being promoted by one of the bus operators.
- Stockport town centre to Wilmslow and Handforth
- Macclesfield to Manchester Airport (via Poynton)

Any such new bus services would add to the economic benefit to public transport, reduce travel by private car and contribute to reducing the carbon impact of the new relief road. This will directly address one of the scheme's second tier objectives, which is to:

Support lower carbon travel:

- Improve public transport accessibility (reduced journey times for buses) and increase bus usage between Stockport town centre and Manchester Airport

3.4.4. Spatial Distribution of Benefits

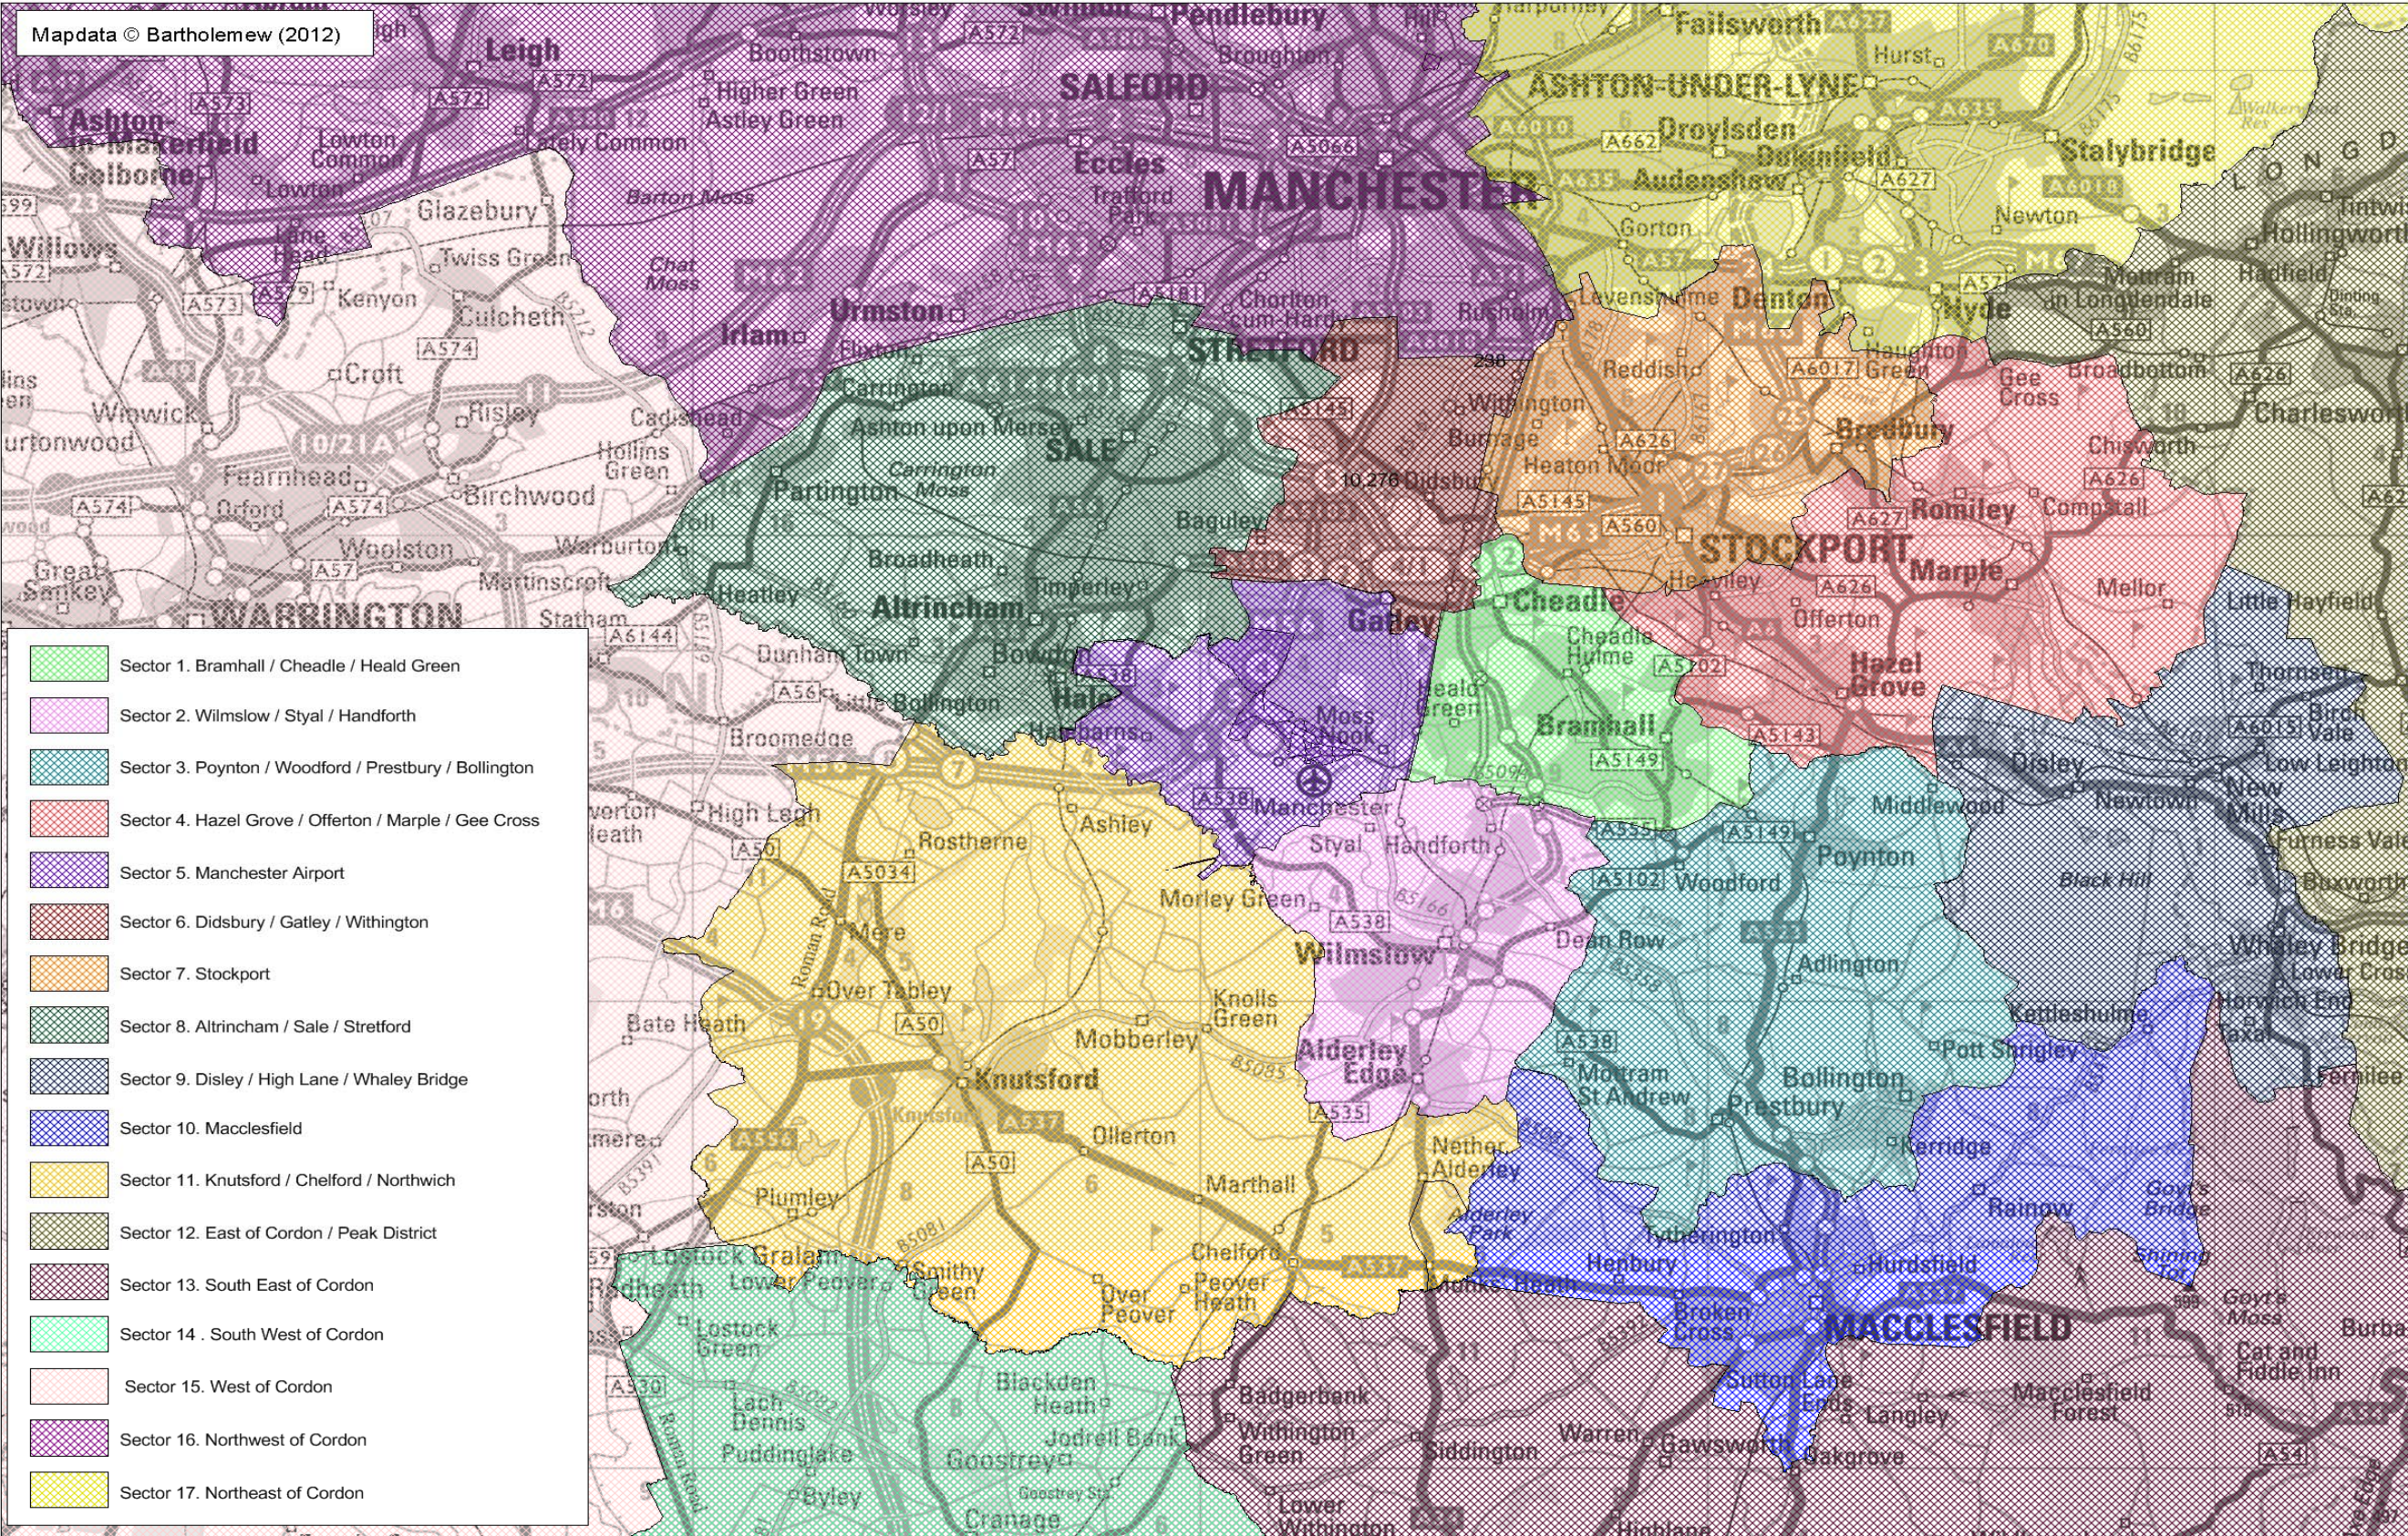

The economic assessment is concerned primarily with the overall economic summary statistics, culminating in a BCR that reflects the value for money of the scheme proposals. However, it is important to understand from where these benefits have been derived. One way of doing this is to compare the benefits generated by different geographical areas across the study area.

This 'sector analysis' has been undertaken using the following 'geographical' areas (and shown graphically in Figure 3.1 below).

- Sector 1 - Bramhall / Cheadle / Heald Green;
- Sector 2 - Wilmslow / Styal / Handforth;
- Sector 3 – Poynton / Woodford / Prestbury / Bollington;
- Sector 4 – Hazel Grove / Offerton / Marple / Gee Cross;
- Sector 5 – Manchester Airport;
- Sector 6 – Didsbury / Gatley / Withington;
- Sector 7 – Stockport;
- Sector 8 – Altrincham / Sale / Stretford;

- Sector 9 – Disley / High Lane / Whaley Bridge;
- Sector 10 – Macclesfield;
- Sector 11 – Knutsford / Chelford / Northwich;
- Sector 12 – East of 'Cordon' / Peak District;
- Sector 13 – South East of 'Cordon';
- Sector 14 – South West of 'Cordon';
- Sector 15– West of 'Cordon';
- Sector 16 – North West of 'Cordon'; and;
- Sector 17 – North East of 'Cordon'

Figure 3-1 A6MARR Traffic Model - TUBA 'Sector' Boundaries

Tables 3.9, 3.10, 3.11 & 3.12 provide a summary of the total benefits generated by trips from and to each of the above sectors at 2017 and 2032 (the scheme 'opening' and 'design' years).

Benefits from the proposed A6MARR scheme are shown to be greatest for traffic travelling to/from local centres adjacent to the route of the scheme such as Bramhall, Cheadle, Hazel Grove, Marple, Wilmslow, Styal and Handforth among others. Significant benefits are also observed for trips originating and destined for the central Stockport area. These benefits are accrued due to traffic using the proposed SEMMMS scheme as an attractive and viable alternative for access to these local centres and enabling longer distance through trips to re-route away from these local centres and the existing congested local road network.

This pattern of benefits is the same for both the opening year of 2017 and the design year of 2032. The distribution of benefits is also broadly similar across both the Low Growth and High Growth scenarios.

Detailed sector-to-sector result tables are provided in Appendix C.

Table 3-9 Scheme Origin Trip TUBA Based PVB (£000s) at Sector Level - 2017

Sector	Preferred Option	Low Growth	High Growth
Bramhall / Cheadle / Heald Green	1481	932	2117

East of Cordon / Peak District	574	458	572

South East of Cordon	374	1136	1632
South West of Cordon	-50	230	988
West of Cordon	1055	1008	1796
Northwest of Cordon	828	908	2564
Northeast of Cordon	1345	2200	3394
Total	18479	17259	43279

The main benefits are shown to accrue to users travelling to and from the local centres around the proposed scheme. This is intuitive, as the scheme provides drivers with an alternative option to their normal route and hence, some vehicles will be taken off existing roads, reducing travel time for those who continue to use these existing roads as part of their route.

Table 3.13 provides a summary of the combined total benefits generated by trips from and to each of the 17 sectors for 2017 and 2032 (the scheme 'opening' and 'design' years).

4. Conclusions

4.1. Overview

A series of traffic models have been developed to assess proposals for the potential A6MARR scheme. Two sensitivity tests assessing a Low and High Growth scenario have also been undertaken. The future year traffic models have been used to generate demand and cost data, which forms the basis of an economic assessment described in this report.

4.2. Scheme Benefits

The preferred option scheme produces a PVB of £943 million. Taking into account the total scheme costs, it produces a scheme NPV of £736 million and a **BCR of 4.55**. This represents '**very high**' value for money against DfT guidance.

The scheme is forecast to reduce the number of accidents on the highway network across the study area, resulting in 556 fewer personal injury accidents and generating £23 million of accident savings benefits as a consequence.

This economic assessment has shown that the A6MARR scheme provides very good value for money, exceeding the DfT criterion for 'very high' value for money.

Appendix B. Derivation of Annualisation Factors

Annualisation factors for expanding modelled benefits across the year can be based on default values as recommended in the TUBA guidance, or on locally-observed traffic data. In cases where AM, inter-peak and PM peak models represent an average hour during each time period, default factors are easy to justify. The AM and PM peak periods are assumed to represent the periods 0700-1000 and 1600-1900 respectively, that is, three hours in each peak period. A factor of three would be applied to an AM/PM average hour model, to reflect the fact that average conditions occur on three hours of the day. Assuming 253 working days across the year (365 days less 104 weekend days and 8 Bank Holidays), an annualisation factor of 759 would be adopted for the AM and PM models (253 days x 3 peak hours).

The inter-peak is represented by the period 1000-1600, that is, a six-hour period, so total daily inter-peak benefits would be derived by applying a factor of 6 to the inter-peak modelled hour benefits. Assuming the same 253 working days across the year, a factor of 1518 would be adopted for the inter-peak (253 x 6 inter-peak hours).

For the SEMMMS A6 to Manchester Airport Relief Road Scheme, default values would be potentially misleading for the AM peak traffic model, as they represent the single peak hour, rather than average morning peak traffic conditions. In such instances, the benefits generated by the scheme proposals are likely to be overestimated, as peak hour conditions are unlikely to be replicated for all three hours of the AM peak period. The factor used to annualise peak hour modelled benefits, therefore, is lower than the default factors one would apply to 'average hour' models, as it takes into account the higher than average proportion of traffic in the peak hour relative to the respective three-hour peak periods.

For the inter-peak and PM Peak average hour models, however, the default factor of 1518 and 759 respectively are valid as they are based on an average of inter-peak and PM peak hours and have therefore been adopted for this assessment.

Annualisation factors for a Saturday and an off peak week day period of 19:00 – 07:00 have also been calculated and used as part of the TUBA assessment.

The annualisation factors used for each time period are as follows:

- Weekday AM Peak: 672;
- Weekday PM Peak: 759;
- Weekday Inter-Peak: 1518;
- Off Peak: 633; and
- Weekend: 520.

The off peak and Weekend annualisation factors have been specifically adjusted for this study. TRADS data was collated for 21 sites within the area of interest, most notably on the M56, M60 South and the A5103. The TRADS data enabled analysis of full 24 hour flow profiles for both weekday and weekend traffic.

Both an average weekday off peak (19:00 – 07:00) hourly flow and an average weekend hourly flow was calculated. These were compared to an average inter-peak hour flow to obtain an 'inter-peak to respective hour' factor. This factor was 0.319 for off-peak and 0.561 for weekend. The factors were then multiplied by the number of hours in the day, days in the week and weeks in the year for each respective time period. The resulting annualisation factors were 994 for off-peak and 1401 for weekend. Table B.1 below summaries the derivation of 'off-peak' and 'weekend' annualisation factors.

Table B-1 Derivation of Off-Peak and Weekend Annualisation Factors Table

Factor Variable	Off-peak	Weekend
IP hour to respective hour	0.319	0.561
Hours in day	12	24
Days in week	5	2
Weeks in year	52	52
Annual Factor	994	1401

An analysis of a typical weekend traffic flow profile revealed that ‘inter-peak’ traffic conditions are met for approximately 5 hours (for the period 1200 to 1700 as shown in the figure below). It was therefore felt that an annualisation factor of 1401 hours would dramatically over-estimate the numbers of weekend hours and as such distort the level of scheme benefit generated for the Weekend period. For the purposes of this appraisal it was decided to use the following assumptions to generate the weekend annualisation factor – 5 hours (of inter peak travel volume conditions) x 2 weekend days x 52 weeks = 520.

A similar assumption was made to generate the off-peak annualisation factor, as again it was felt that a figure of 994 was too high and distort an scheme benefit profile. An analysis of TRADS data showed that there were approximately 2.5 hours in the off peak period that match a typical inter peak flow profile. This was then multiplied by 253 (off peak week days in a year) to generate an off peak annualisation factor of 633.

Figure B.1 Comparison of Weekday and Weekend Traffic Volumes (TRADS Data)
